Key words: biocontrol, *Botrytis cinerea*, *Monilinia laxa*, spoilage, antagonistic yeast

Postharvest fruit loss due to spoilage is mainly attributed to fungal infections. Synthetic chemicals can be used to preserve fruits, but they are expensive and pose risks to human health. The replacement of these chemicals by safer and cost-effective biocontrol agents is now a priority. This study investigated the physiological characteristics of *Pichia kluvyeri* and its potential use as a biofungicide. The antagonistic effect of *P. kluvyeri* against *Botrytis cinerea* and *Monilinia laxa* was tested on yeast peptone dextrose agar, grapes, apples, and pears. Yeast growth was variably possible at different temperatures, pH, and salinity levels. Strain-dependent antagonistic responses were observed on agar plates, where *M. laxa* was the more sensitive fungus to the antagonistic yeast. *P. kluvyeri* demonstrated strong physiological properties under stressful temperature, pH, and salinity conditions. Preventive applications of *P. kluvyeri* to apples were 95% effective against *B. cinerea* and 100% effective against *M. laxa*. Fruit type-dependent responses were evident on pears. Similarly, preventive application on grapes was also effective against the fungal pathogens studied. In general, the antagonistic responses were both fungus- and treatment- (curative and preventive) dependent. Therefore, the preventive use of *P. kluvyeri* against post-harvest fruit-fungal infections proved to be an effective method for biological control of grapes, apples, and pears against fungal spoilage organisms *Botrytis cinerea* and *Monilinia laxa*.

INTRODUCTION

Fruits are important in a balanced diet, as they are generally rich in fibre, minerals, water, and vitamins. Unfortunately, the majority of fruits are lost or their shelf life is shortened due to spoilage by fungal pathogens [Zhu, 2006]. While pre-harvest infections and spoilage is a problem [Fourie et al., 2002], 25% of fruit spoilage occurs during post-harvest handling and is of major concern to the global agricultural industry [Droby, 2005; Singh & Sharma, 2007]. Prior to thermal preservation techniques, *Penicillium expansum* was responsible for complete post-harvest spoilage of apples globally [Morales et al., 2007]. In table grapes, apples, and many other crop species, *Botrytis cinerea*, *Colletotrichum acutatum* and *Rhizopus stolonifer* are usually responsible for spoilage [Sharma et al., 2009; Williamson et al., 2007]. Additionally, brown rot and grey mould of South African stone fruits are linked to *Monilinia laxa* and *B. cinerea*, respectively [Fourie et al., 2002].

Fruit-derived beverages are also subject to microbial spoilage, all which impacts negatively on the economy [Parveen et al., 2016]. *Dekkera, Zygosaccharomyces, Picha, and Hanseniaspora* species are the most common spoilage organisms of fruit-derived beverages [Du Toit & Pretorius, 2000; Sáez et al., 2010].

The reduction of microbial spoilage in fruits is conventionally achieved by treatment with chemical fungicides. However, organisations, such as the World Health Organization and the European Economic Community highlighted major health-related concerns associated with their usage in food industries [Ciani & Fatichenti, 2001]. In addition, the resistance of some pathogens to chemical preservatives often prompts an increase in chemical preservative dosages, above acceptable limits [Benito et al., 2009], which can negatively affect product quality. As a result, safer, cheaper, and cost-effective alternatives have recently been the central focus. The use of safer biological systems such as yeast is another potential
source of biocontrol agents against fruit and fruit-derived beverages [Ciani & Fatichenti, 2001; Comitini et al., 2004a; Grzegorczyk et al., 2017; Mehlomakulu et al., 2014; Parveen et al., 2016]. Thus far, several yeasts have been reported to have antagonistic properties against fruit and fruit-derived beverages spoilage pathogens [Aloui et al., 2015; Cordero-Bueso et al., 2017; El Ghaouth et al., 2004; Mehlomakulu et al., 2014; Mewa-Ngongang et al., 2017, 2019a]. Yeasts are excellent biocontrol agents because their growth requirements are simple and their growth kinetics on many fruits and in beverages are competitive [Liu et al., 2013; Muccilli & Restuccia, 2015]. An additional advantage of biological systems is their ability to produce extracellular compounds with antimicrobial properties against many fruit pathogens such as spoilage yeasts, bacteria, and fungi [Comitini et al., 2004a,b; Grzegorczyk et al., 2017; Mehlomakulu et al., 2014].

Several authors have highlighted the importance of nonSaccharomyces yeasts in addressing food spoilage [Mewa-Ngongang et al., 2017, 2019b; Oro et al., 2014]. Their widespread use in the food industry, their ability to handle and grow quicker than spoilage organisms, and their ability to produce killer toxins have been widely acknowledged. The biotechnological potential of Pichia kluyveri has been highlighted as a producer of aromatic and growth inhibition compounds in beverages [Crafack et al., 2013; Jolly et al., 2014]. The aim of this study was to evaluate the physiological properties of P kluyveri and to assess its potential in suppressing post-harvest fungal growth of B. cinerea and M. laxa on yeast peptone dextrose agar, apples (Golden delicious), table grapes (Regal seedless), and pears (Packham's Triumph).

**MATERIALS AND METHODS**

**Strain selection and maintenance**

Previously isolated from Marula (Sclerocarya birrea) juice, the yeast P kluyveri Y1164 was selected after screening several yeasts from the ARC Infruitec-Nietvoorbij yeast culture collection (The Fruit, Vine and Wine Institute of the Agricultural Research Council, Stellenbosch, South Africa). B. cinerea and M. laxa were supplied by the Post-harvest Pathology Laboratory (ARC Infruitec-Nietvoorbij). Yeast cells and spores of B. cinerea and M. laxa were propagated at 25°C and maintained at 4°C on yeast peptone dextrose agar (yeast extract 10 g/L, peptone 20 g/L, dextrose 20 g/L, and 20 g/L agar) (YPDA, Biolab, Merck, Modderfontein, South Africa). The pH was 6.5 after autoclaving.

**Yeast cells and fungal spore preparation**

To investigate the antagonistic effects of P kluyveri on fungal growth, yeast cells were cultivated in YPD broth (Biolab, Merck) at a pH of 6.5 for 24 h at 25°C, using a rotary shaker (150 rpm). Fungus spores were detached from the YPDA cultures and suspended in sterile distilled water. A microscope (SN-EU 1712504, BioBlue Lab, Euromex Microsystems, Arnhem, Holland) and a Neubauer counting chamber were used to determine the cell or spore concentrations at 400× magnification.

**Characterisation of physiological properties: Salinity, pH, and temperature**

The ability of P kluyveri to grow under different salinity (0.05, 0.10, 0.15, and 0.20 g/mL NaCl), pH (1, 2, 3, 7, and 8), and temperature (5, 15, 30, and 40°C) conditions was investigated. A pre-inoculum was prepared by transferring a wire loopful of P kluyveri cells into a test tube containing 10 mL of sterile YPD broth and incubated without agitation at 28°C for 24 h. Subsequently, test tubes containing 5 mL of pH- and saline-adjusted YPD broth (in triplicate) were inoculated at a final concentration of 105 cells/mL of P kluyveri and incubated without agitation at 28°C for 7 days. For the determination of growth at various temperatures, test tubes containing 5 mL of YPD broth were inoculated as mentioned above, but incubated at different temperatures for 7 days. After incubation, cell concentrations were determined microscopically using a Neubauer counting chamber. Based on the initial inoculum of 105 cells/mL, low, medium, and high growth was defined as those concentrations ranging from 105 to 108, 104 to 106, and 103 to 104 cells/mL, respectively.

**Antagonistic effect of P kluyveri on fungal growth: Plate assay**

This assay was adapted from Medina-Córdova et al. [2016]. YPDA plates were prepared and a mycelial culture disc (5 mm) of either B. cinerea or M. laxa was placed 2.5 cm away from the plate edges. A volume of 15 µL yeast cells suspension (106 cells/mL) was deposited 3 cm from the disc and the plates were sealed with laboratory film (Parafilm®). After incubation at 28°C for 7 days, the diameter of the fungal growth zones was measured. Negative controls were prepared by seeding a mycelial disc at the centre of the YPDA plate under analogous incubation conditions. The antagonistic effect of the yeast was measured in terms of the comparative reduction in fungal growth (diameter) between treatments and negative controls (average of three replicates).

**Preventive and curative treatments: Apple, grape, and pear bioassays**

Golden Delicious apples (Malus domestica) and Packham’s Triumph pears (Pyrus communis ‘Bosc’) were obtained from a local producer, Two-A-Day Group Ltd (Grabouw, South Africa). Regal Seedless table grapes (Vitis vinifera) were obtained from the Cultivar Development Division of ARC Infruitec-Nietvoorbij. Apples and pears (10 replicates consisting of three pears/apples per replicate) were washed, dried, and sprayed with 70% ethanol and uniformly wounded with a sterile cork borer (approximately 5 mm diameter and 3 mm deep). The ethanol was allowed to dry prior to the next step. After wound infliction, fruits were allowed to dry before undergoing preventive or curative treatments. For preventive treatments, wounded fruits were inoculated with 20 µL (105 cells/mL) of P kluyveri cell suspension using a micropette and incubated overnight at room temperature. Subsequently, the yeast cells were allowed to colonise the fruits for 24 h before inoculation with 20 µL (105 cells/mL) of B. cinerea or M. laxa suspension. For curative treatments, the wounded fruits were inoculated with 20 µL (106 fungal spores/mL) of B. cinerea or M. laxa, incubated for 24 h and then inoculated
with 20 µL (10^6 cells/mL) of *P. kluyveri* suspension. Treated fruit was maintained at -0.5°C for 4 weeks, and then stored at room temperature (±20°C) for 7 days, to simulate shipping conditions and shelf life in a commercial setting. Positive results were characterised by the absence of fungal development on the fruit surfaces. For preventive and curative treatments/bioassays, negative controls were prepared by inoculating fruits with 20 µL (10^6 fungal spores/mL) of *B. cinerea* or *M. laxa* suspensions under similar maintenance and storage conditions. During the incubation period for all the treatments, there was an 80% relative humidity. Comparative analysis of the differences in lesion diameters/growth inhibition between the negative controls and inoculated fruits was done to determine if the yeast is a successful biocontrol agent against *B. cinerea* and *M. laxa*. For both treatments, the percentage inhibition was obtained, considering that the negative control was 100% of the lesion diameter. Table grapes (20 replicates consisting of 10 grape berries per replicate) were uniformly wounded with a sterile needle (2 mm diameter, 1 wound per berry) and allowed to dry prior to preventive and curative treatments. For preventive treatments, wounded grapes (10 grapes per replicate) were sprayed with 10 mL (10^6 cells/mL) of *P. kluyveri* cell suspension, incubated overnight at room temperature and sprayed with 10 mL (10^6 cells/mL) of *B. cinerea* or *M. laxa* suspension. For curative treatments, the wounded grapes were sprayed with 10 mL (10^6 fungal spores/mL) of *B. cinerea* or *M. laxa*, incubated for 24 h, and then sprayed with 10 mL (10^6 cells/mL) of *P. kluyveri* suspension. The negative controls (10 berries each) were prepared by spraying the fungal spores on the wounded berries without yeast treatment. All grape treatments were also maintained at -0.5°C for 4 weeks, and then stored at room temperature (±20°C) for 7 days. The antagonistic properties of *P. kluyveri* were analysed visually by assessing the grape colour changes and fungal development on treated grapes.

### Statistical analysis

The experiment was randomised and the data for each experiment was analysed separately. To determine whether there were significant differences within the physiological parameters (pH, temperature, and salinity), analysis of variance was performed using general linear means procedure of SAS version 9.4 (SAS Institute Inc, Cary, NC, USA). Fisher’s least significant difference (LSD) values were calculated at the 5% probability level (p=0.05) to facilitate comparison between treatment means.

### RESULTS AND DISCUSSION

#### Physiological properties of *P. kluyveri*

The results in Table 1 show growth characteristics of *P. kluyveri* under different pH, saline, and temperature conditions in YPD. One of the required properties of biocontrol agents (e.g., yeast) is the ability to tolerate a broad spectrum of the aforementioned conditions. These conditions are fruit type-dependent and critical during postharvest because they affect the growth of both antagonistic yeasts and fruit fungal pathogens. Prior to postharvest control treatments, it was important to establish whether yeast growth was possible under a very wide spectrum of conditions. Relatively low yeast count was observed at 5°C (1.55×10^5 cells/mL) and 40°C (1.58×10^7 cells/mL), at pH 1 (1.64×10^6 cells/mL), and 0.15 g/mL (1.37×10^7 cells/mL) and 0.20 g/mL (1.07×10^6 cells/mL) salinity. A moderate count was observed at 0.10 g/mL salinity (1.41×10^7 cells/mL). The highest cell counts were obtained at 15°C (3.75×10^7 cells/mL) and 30°C (3.17×10^7 cells/mL), at pH 2 (1.86×10^7 cells/mL), pH 3 (1.74×10^7 cells/mL), pH 7 (5.50×10^6 cells/mL), pH 8 (4.55×10^6 cells/mL), and 0.05 g/mL salinity (4.72×10^6 cells/mL). The optimal growth temperature range of *P. kluyveri* corresponds to the South African mean annual temperatures between 17–22°C ["CapeFarmMapper," n.d.]. Meaning that yeast growth and antagonistic properties can be stimulated under most agricultural and postharvest conditions of South Africa.

The ideal pH and saline conditions for *P. kluyveri* also relate to the intrinsic properties of most fruits, i.e., pH 3.2–4.5 and <0.1 g/mL salt, respectively [Kessels, 2003]. These findings were also comparable to the findings of Psani & Kotzekidou [2006] where the large majority of *Debaryomyces hansenii* (15 strains) and *Torulaspora delbrueckii* (32 strains) were able to grow optimally at 15°C, pH 2.5, and 0.1 g/mL NaCl. Previously, both yeast growth and the killer properties of yeast were associated with changes in environmental conditions such as temperature, salinity, and pH [Tipper & Bostian, 1984]. As in the current study, Çelik et al. [2017] also reported insignificant growth rates of most yeast strains (*P. kluyveri, Candida zemplinina, P. occidentalis, and Saccharomyces cerevisiae*) when the temperature was below 15°C under grape-must fermentation conditions (pH 3.18). Although this study is the first to report on some antagonistic

properties of *P. kluyveri*, our findings on the physiological properties of *P. kluyveri* were not surprising, since another *Pichia* species (*P. anomala* J121) was previously considered efficient biocontrol yeasts because of their ability to grow under harsh conditions, i.e. temperature (3–37°C), pH (2.0–12.4), and water activity of 0.92 (NaCl) and 0.85 (glycerol) [Fredlund et al., 2004].

**Antagonistic effect of *P. kluyveri* against fungal growth**

Figure 1 and Figure 2 show the antagonistic effect of *P. kluyveri* against two fruit fungal pathogens, *B. cinerea* and *M. laxa*. The mean growth diameter on the negative control was 45.58 and 63.42 mm for *M. laxa* and *B. cinerea*, respectively (Figure 1). The most sensitive fungus to the antagonistic yeast was *M. laxa*, which showed a growth inhibition of 54.6% after 7 days of incubation (Figure 2). Compared to the negative control (p<0.05), 44.5% growth inhibition was observed against *B. cinerea*. Although *B. cinerea* (negative control) grew faster than *M. laxa* on YPDA, the antagonistic effect of *P. kluyveri* was still maintained and seemed independent of fungal growth kinetics. Additionally, species-dependent antagonistic responses were evident on solidified medium assays. Previously, the screening and the identification of antimicrobial producing yeasts such as *Candida intermedia* [Huang et al., 2011] and *Sporidiobolus pararoseus* [Huang et al., 2012] was achieved on solid medium. A similar study by Mewa-Ngongang et al. [2019b] also demonstrated the broad antagonistic effect of *P. kluyveri* on solidified plate assays, therefore supporting the findings of this research. Although the pre-screening of biocontrol agents on agar media is common, more rapid and cost-effective methods still need to be developed.

**Preventive and curative treatments: Apple bioassay**

As shown in Figure 3 and Figure 4, *P. kluyveri* applied preventively, was effective in suppressing fungal growth to 95.12% (Lesion diameter, LD=3.29 mm) and 100% (LD=0.0 mm) for *B. cinerea* and *M. laxa*, respectively. The curative treatments were not as effective, since growth suppression of *B. cinerea* was only 51.32% (LD=32.77 mm) and 45.68% (LD=26.49 mm) for *M. laxa*, compared to the negative controls. As shown in Figure 3 and Figure 4 preventive/curative biocontrol treatments against both fungal pathogens (*B. cinerea* and *M. laxa*) followed similar trends where smaller lesions were observed for *M. laxa*. Gril et al. [2008] also categorised *M. laxa* as a pathogen of apple fruits, but not its principal or preferred host. Sansone et al. [2018] proved that the biocontrol of *B. cinerea* BNM 0527 was more effective under preventive rather than curative treatments on apples. These authors also showed a 75% and 48% spoilage reduction by *Rhodosporidium fluviale* as preventive and curative treatments, respectively. These results confirm the old notion that says, ‘prevention is better than cure’.

**FIGURE 1.** Diameters of *Botrytis cinerea* and *Monilinia laxa* growth zones (negative control) and growth of these fungi in the presence of *Pichia kluyveri* Y1164 (treatment) on yeast peptone dextrose agar plates.

**FIGURE 2.** Photograph of the inhibition assay on yeast peptone dextrose agar plates showing the inhibition potential of *Pichia kluyveri* Y1164 on *Botrytis cinerea* and *Monilinia laxa*. Growth inhibition is given as the percentage difference between fungal growth diameter of *Botrytis cinerea* (a) and *Monilinia laxa* (b) controls as well as *Botrytis cinerea* (c) and *Monilinia laxa* (d) treatments. Each plate is a representative example of three replicates.

**FIGURE 3.** Growth inhibition of *Botrytis cinerea* and *Monilinia laxa* on apples with the associated level of biological control by *Pichia kluyveri* Y1164 used as preventive and curative treatments. Values are the average of 10 replicates consisting of three apples per replicate ± standard deviation (n=30). The lesion diameters, from which the percentage inhibition was obtained, are shown in Figure 4.
Preventive and curative treatments: Table grape bioassay

The antagonistic effect of *P. kluyveri* applied as preventive and curative grape treatments on the growth of *B. cinerea* and *M. laxa* are shown in Figure 5. A 100% growth inhibition was observed, which was demonstrated by the absence of spoilage for the preventive treatments. Translating to effective control of both *B. cinerea* and *M. laxa* infections, compared to the controls. Slightly different observation was made on the curative treatments where it would be important to mention that the result interpretation in this part was also based on visual observations whereby, a jar was considered as a mini bunch of grape berries that was inspected for decay not as single fruit like in the case of apples and pears. One out of 20 jars infected with *B. cinerea* in the curative treatment showed signs of spoiled berries (95% inhibition), while a 100% inhibition was observed for the curative treatments of *M. laxa*. This result is comparable to the 100% suppression of *Aspergillus carbonarius, Colletotrichum acutatum,* and *Rhizopus stolonifer* growth on grapes by *Candida zemplinina, Candida pyralidae, Saccharomyces cerevisiae,* and *P. kluyveri* [Fiori et al., 2014; Mewa-Ngongang et al., 2019b; Zhu et al., 2015]. Although preventive results were notable, curative biocontrol applications resulted in substandard grape colour and texture, although spoilage was vastly minimised. It is also plausible that, apart from antagonistic properties of *P. kluyveri*, volatile compounds [Fiori et al., 2014; Lutz et al., 2013], hydrolytic enzymes [Hernández et al., 2008], mycotoxins [Thompson et al., 2013] or proteases [Buzzini & Martini, 2002] may have affected fungal growth. The results from this study also showed the effectiveness of *P. kluyveri* against *B. cinerea* and *M. laxa* growth and the advantage of preventive treatments during fruit processing.

Preventive and curative treatments: Pear bioassay

The bioassay with pear fruits confirmed the antagonistic effect of *P. kluyveri* on *B. cinerea* and *M. laxa*, with a significant (p<0.05) reduction in lesion diameter when applied as preventive treatments (Figure 6 and Figure 7). As a preventive treatment, *P. kluyveri* exhibited a 73.16% (LD=9.21 mm) and 78.65% (LD=7.07 mm) inhibition against *B. cinerea* and *M. laxa*, respectively. Curative treatments showed a 58.59% (LD=14.21 mm) and 52.08% (LD=15.45 mm) inhibition against *B. cinerea* and *M. laxa*, respectively. Enhanced control for preventive treatments could be due to the ability of the yeasts to quickly colonise the wound, release antimi-crobial substances, and successfully outgrow fungal pathogens. Therefore, the use of *P. kluyveri* as a preventive treatment can provide an effective strategy to reduce post-harvest decay of pears. Results suggest that the yeast competes with the fungal pathogens for space and nutrients. However, it is also possible that *P. kluyveri* produced secondary metabolites (e.g. diffusible compounds) with antifungal properties [Andrade et al., 2014; Nally et al., 2015; Núñez et al., 2015].
FIGURE 5. Photograph of the jars showing table grapes spoilage caused by *Botrytis cinerea* and *Monilinia laxa* and the associated biological control of *Pichia kluyveri* Y1164 against *Botrytis cinerea* (c) and *Monilinia laxa* (e) preventive treatments as well as *Botrytis cinerea* (d) and *Monilinia laxa* (f) curative treatments. Twenty replicates consisting of 10 grape berries per replicate were tested against both *Botrytis cinerea* (a) and *Monilinia laxa* (b) controls. Each set displayed in this figure is a representative example after 4 weeks at -0.5°C and then at room temperature (±20°C) for 7 days.

FIGURE 6. Growth inhibition of *Botrytis cinerea* and *Monilinia laxa* on pears with the associated level of biological control by *Pichia kluyveri* Y1164 used as preventive and curative treatments. Values are the average of 10 replicates consisting of three pears per replicate ± standard deviation (n=30). The lesion diameters, from which the percentage inhibition was obtained, are shown in Figure 7.
CONCLUSIONS

The biocontrol yeast *Pichia kluyveri* Y1164 inhibited *B. cinerea* and *M. laxa* growth on apples, pears, and table grapes when applied preventively. However, *Pichia kluyveri* Y1164 was not as effective when applied as a curative treatment. Biological control can be considered as a preventive strategy to reduce postharvest fungal spoilage of fruits. Exploring pre-harvest efficacy of the biocontrol yeast *Pichia kluyveri* Y1164, as well as its efficacy against other fruit fungal pathogens can be investigated in future studies.
